*From continuum to semi-discrete equations.* In the context of linear solid dynamics, the spatial discretization of the governing partial differential equations (PDEs) using the Finite-Element Method (FEM) [2], results in

$$\mathbf{M}\mathbf{x}''(t) + \mathbf{C}\mathbf{x}'(t) + \mathbf{K}\mathbf{x}(t) = \mathbf{F}(t), \quad (1)$$

a system of second-order differential equations in time, where  $\mathbf{x}(0) \in \mathcal{X}_0$  and  $\mathbf{x}'(0) \in \mathcal{V}_0$  are the sets of initial displacements and velocities,  $\mathbf{x} \in \mathbb{R}^n$  is the state vector, and  $\mathbf{M}$ ,  $\mathbf{C}$  and  $\mathbf{K}$  are the mass, damping and stiffness matrices, respectively. Depending on the problem and the mesh size,  $n$  is typically between  $10^2$  and  $10^5$ .

*Representing solutions with sets.* In [5] we present a novel approach for time integration of solid heat transfer and structural dynamics equations based on reachability analysis techniques [1]. These methods are implemented in ReachabilityAnalysis.jl, a core package of JuliaReach. Reachability is a modern computational approach where solutions to differential equations are represented using sets. The set-based conservative time integration of Eq. (1) returns solution sets (*flowpipes*) that include all exact trajectories, with convergence to the true reachable states as the time step decreases.

Fig. 1: Diagram of two degrees of freedom and Rayleigh damping.

*Minimal example.* We solve the system in Fig. 1 loaded with a Heaviside step function. Given the FEM assembled matrices (Line 3), the range of variation of the external loads (Line 4) is 10% around the nominal value 1. Initial displacements and velocities for both masses belong to the interval  $[-0.5, 0.5]$  (Line 5). The initial-value problem is instantiated and homogenized as described in [5].

```

1 using ReachabilityAnalysis
2 m = 0.25; k = 2.0
3 M = [2m 0; 0 m]; K = [2k -k; -k k]; C = (M+K)/20
4 F = [0.0, 1.0]; ΔF0 = Interval(0.9, 1.1)
5 U0 = BallInf(zeros(4), 0.5)
6 sys = SecondOrderLinearContinuousSystem(M, C, K, F)
7 prob = InitialValueProblem(homogenize(sys), U0 × ΔF0)
8 solA = solve(prob, 50, LGG09(δ=5e-2, dirs=:box, dim=5))
9 solB = solve(prob, 50, LGG09(δ=5e-2, dirs=:oct, dim=5))

```

Fig. 2: Flowpipe using canonical directions projected on time (top), and using octagonal directions at node 1 (bottom). We additionally plot random simulations.

*Solution method.* To illustrate the flexibility of our approach, two algorithm choices are considered, both relying on support functions [7] (LGG09 algorithm in Lines 8-9). `solA` contains the flowpipe efficiently computed along box directions  $\pm e_1 = [\pm 1, 0, 0, 0]^T$ , while `solB` contains the projection of the flowpipe for node 1 coordinates. To improve the accuracy, the latter method uses octagonal template directions.

*Perspectives.* We envision to model variations in mass and stiffness parameters using interval methods [4, 6]. Probabilistic reachability, and modeling nonlinear behaviors using state-space abstraction methods, are also planned. We think that integrating the tool with third-party open source FEM software, such as ONSAS [3], is the next key step for solving real world problems using reachability.
